PWr Week 3

Algorithms and Data Structures,

 $Laboratory-List \ 3$

1. Write a program with below operations for a two-way **unordered** cycled list (without sentinel):

- a. **void** init(List2W& 1) which initialize the list 1.
- b. **void** insertHead(List2W & 1, **int** value) insert an element with value as a head (first element) in a list 1.
- c. **bool** deleteHead(List2W & 1, int &value) remove a head (first element) from a list and return it in the value parameter. Return true if operation was successful, otherwise return false;
- d. **void** insertTail(List2W & 1, **int** value) insert an element with value as a tail (last element) in a list 1.
- e. **bool** deleteTail(List2W & 1, int &value) remove a tail (last element) from a list and return it in the value parameter. Return true if operation was successful, otherwise return false;
- f. int findValue(List2W & 1, int value) find first element in list 1 with value and return its position (starting from 0). If there is no such element, return -1;
- g. void removeAllValue(List2W & 1, int value) remove from list 1 all elements which are equal to value. If there is no such element, do nothing.
- h. **void** showListFromHead(List2W & 1) show elements of list 1 starting from the head. The values are written in one line, after every value has to be a coma. If a list is empty the line is empty. The line ends with newline character.
- i. **void** showListFromTail(List2W & 1) show elements of list 1 starting from the tail. The values are written in one line, after every value has to be a coma. If a list is empty the line is empty. The line ends with newline character.
- j. void clearList(List2W & 1) remove all elements from list l.
- k. **void** addList(List2W & 11, List2W & 12) move all elements from list 12 to list 11. The order of elements does not change, elements from 12 are after elements from 11. After this operation the list 12 is empty. If 11 and 12 are the same list do nothing.

Format of a stream on judgment system is presented in appendix 1. Prepare 2-3 interesting tests using this format.

For **10 points** present solutions for this list till **Week 4**.

For 8 points present solutions for this list till Week 5.

For 5 points present solutions for this list till Week 6.

After Week 6 the list is closed.

Appendix 1

The solution will be automated tested with tests from console of presented below format. The test assumes, that there are up to X different lists, which there are created as the first operation in the test. Each list can be initialized separately.

If a line is empty or starts from '#' sign, the line have to be ignored. In any other case, your program should print an exclamation mark and write (copy) introduced a line and then, depending on the command follow the correct procedure / function.

If a line has a format:

GO n

your program has to create n lists (without initialization). The lists are numbered from 0 like an array of lists. Default current list is a list with number 0.

If a line has a format:

CH n

your program has to choose a list of a number n, and all next functions will operate on this list. There is n > 0.

If a line has a format:

TN

your program has to call init(1) for current list 1. For any list this operation will be called once.

If a line has a format:

IH X

your program has to call insertHead (1, x) for current list 1.

If a line has a format:

DH

your program has to call deleteHead(l,x) for current list l and if operation was successful write the x value on the console. Otherwise write only "false" in one line.

If a line has a format:

IT x

your program has to call insertTail(1, x) for current list 1.

If a line has a format:

 DT

your program has to call deleteTail(1, x) for current list 1 and if operation was successful write the x value on the console. Otherwise write only "false" in one line.

If a line has a format:

FV x

your program has to call findValue(1,x) for current list 1, and write on output returned value.

If a line has a format:

```
RV x
your program has to call removeAllValue(1,x) for current list 1.

If a line has a format:
SH
your program has to call showListFromHead(1) for current list 1.
```

If a line has a format:

ST

your program has to call showListFromTail(1) for current list 1.

If a line has a format:

CL

your program has to call clearList(1) for current list 1.

If a line has a format:

AD n

your program has to call addList(1, 12) for current list 1 and for list 12 which is the n'th list in the array of lists

If a line has a format:

ΗА

your program has to end the execution, writing as the last line "END OF EXECUTION". Every test ends with this line.

For example for input test:

GO 2
IN
IH 1
IH 2
CH 1
IN
IH 4
AD 0
SH
ST

RV 1

SH ST

CH 0

ST

IT 1 ST

HA

The output have to be:

START

```
!GO 2
!IN
!IH 1
!IH 2
!CH 1
!IN
!IH 4
!AD 0
!SH
4,2,1,
!ST
1,2,4,
!RV 1
!SH
4,2,
!ST
2,4,
!CH 0
!ST
!IT 1
!ST
1,
!HA
END OF EXECUTION
```
